Randomness and Pseudorandomness

Review

Problem:

Integrity of message sent from Alice to Bob

Append bits to message that only Alice and Bob can make

Solution:

Message Authentication Code (MAC)

Practical solution:

Hash-based MAC (HMAC) – $HMAC-SHA256_k(M)$

Where do these random keys **k** come from ... ?

Careful: We're often sloppy about what is "random"

True Randomness

Output of a physical process that is inherently random

Scarce, and hard to get

Pseudorandom Function (PRF)

Sampled from a family of functions using a key

Pseudorandom generator (PRG)

Takes small seed that is really random

Generates a stream (arbitrarily long sequence) of numbers that are "as good as random"

Definition: **PRG** is secure if it's indistinguishable from a random stream of bits

Similar game to PRF definition:

- 1. We flip a coin secretly to get a bit **b**
- 2. If b=0, let s be a truly random stream If b=1, let s be g_k for random secret k
- 3. Mallory can see as much of the output of **s** as he/she wants
- Mallory guesses b,
 wins if guesses correctly

g is a secure PRG if no winning strategy for Mallory*

Here's a simple PRG that works:

```
For some random k and PRF f, output: f_k(0) \parallel f_k(1) \parallel f_k(2) \parallel ...
```

Theorem: If f is a secure PRF, and g is built from f by this construction, then g is a secure PRG.

Proof: Assume f is a secure PRF, we need to show that g is a secure PRG.

Proof by contradiction:

- 1. Assume **g** is not secure; so Mallory can win the PRG game
- 2. This gives Mallory a winning strategy for the PRF game:
 - a. query the PRF with inputs 0, 1, 2, ...
 - b. apply the PRG-distinguishing algorithm
- 3. Therefore, Mallory can win PRF game; this is a contradiction
- 4. Therefore, g is secure

Where do we get true randomness?

Want "indistinguishable from random" which means: adversary can't guess it

Gather lots of details about the computer that the adversary will have trouble guessing [Examples?]

Problem: Adversary can predict some of this

Problem: How do you know when you have enough randomness?

Modern OSes typically collect randomness, give you API calls to get it e.g., Linux:

/dev/random gives output of a PRG, blocking if its entropy estimate is low
/dev/urandom gives output of the same PRG but nonblocking

Review: Message Integrity

Integrity of message sent over an untrusted channel

Alice must append bits to message that only Alice (or Bob) can make

Idealized solution: Random function

Practical solution:

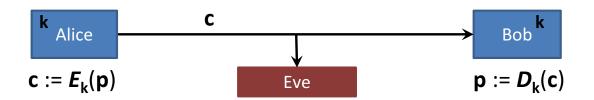

(Hash-based) MAC

 $f_{\mathbf{k}}$ is (we hope!) indistinguishable in practice from a random function, unless you know \mathbf{k}

Confidentiality

Confidentiality

Goal: Keep contents of message **p** secret from an *eavesdropper*

Terminology

- **p** plaintext
- **c** ciphertext
- **k** secret key
- **E** encryption function
- **D** decryption function

Digression: Classical Cryptography

Caesar Cipher

First recorded use: Julius Caesar (100-44 BC)

Replaces each plaintext letter with one a fixed number of places down the alphabet

Encryption: $c_i := (p_i + k) \mod 26$

Decryption: $\mathbf{p_i} := (\mathbf{c_i} - \mathbf{k}) \mod 26$

e.g. (**k**=3):

Plain: go flames + Key: 33 333333 = Cipher: JR IODPHV

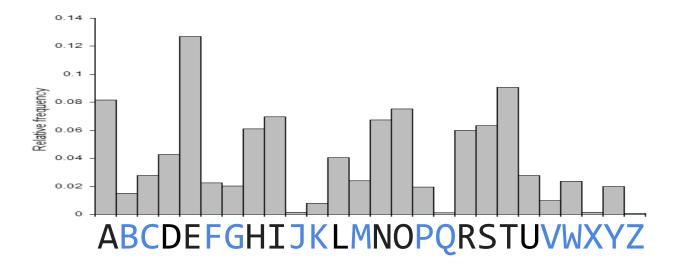

Cryptanalysis of the Caesar Cipher

Only 26 possible keys:

Try every possible **k** by "brute force"

Can a computer recognize the right one?

Use *frequency analysis*: English text has distinctive letter frequency distribution

Later advance: Vigènere Cipher

First described by Bellaso in 1553, later misattributed to Vigenère Called «le chiffre indéchiffrable» ("the indecipherable cipher")

Encrypts successive letters using a sequence of Caesar ciphers determined by the letters of a keyword

For an **n**-letter keyword **k**,

```
Encryption: \mathbf{c_i} := (\mathbf{p_i} + \mathbf{k_{i \mod n}}) \mod 26
Decryption: \mathbf{p_i} := (\mathbf{c_i} - \mathbf{k_{i \mod n}}) \mod 26
```

Example: \mathbf{k} =ABC (i.e. \mathbf{k}_0 =0, \mathbf{k}_1 =1, \mathbf{k}_2 =2) Plain: bbbbb amazon

+Key: 012012 012012 =Cipher bcdbcd anczpp

Cryptanalysis of the Vigènere Cipher

Simple, if we know the keyword length, n:

- 1. Break ciphertext into **n** slices
- 2. Solve each slice as a Caesar cipher

How to find n? One way: Kasiski method

Published 1863 by Kasiski (earlier known to Babbage?)

Repeated strings in long plaintext will sometimes, by coincidence, be encrypted with same key letters

Plain: CRYPTOISSHORTFORCRYPTOGRAPHY

+Key: ABCDABCDABCDABCDABCDABCD

=Cipher: CSASTPKVSIQUTGQUCSASTPIUAQJB

Distance between repeated strings in ciphertext is likely a multiple of key length e.g., distance 16 implies **n** is 16, 8, 4, 2, 1

[What if key is as long as the plaintext?]

Kerckhoff's Principles

1st: The system must be practically, if not mathematically, indecipherable;

2nd: The system must not require secrecy and must not cause inconvenience should it fall into the hands of the enemy;

3rd: The key must be able to be used in communiques and retained without the help of written notes, and be changed or modified at the discretion of the correspondents;

4th: The system must be compatible with telegraphic communication;

5th: The system must be portable, and remain functional without the help of multiple people;

6th: Finally, it's necessary, given the circumstances in which the system will be applied, that it's easy to use, is undemanding, not overly stressful, and doesn't require the knowledge and observation of a long series of rules

"Schneier's law"

"Any fool can invent a cipher that he himself cannot break."

One-time Pad (OTP)

```
Alice and Bob jointly generate a secret,
  very long, string of <u>random</u> bits
  (the one-time pad, k)
```

To encrypt: $\mathbf{c_i} = \mathbf{p_i} \times \mathbf{k_i}$

To decrypt: $\mathbf{p_i} = \mathbf{c_i} \times \mathbf{k_i}$

а	b	a xor b
0	0	0
0	1	1
1	0	1
1	1	0

 $\mathbf{a} \times \mathbf{b} \times \mathbf{b} = \mathbf{a}$ $a \times b \times a = b$

"one-time" means you should never reuse any part of the pad.

If you do:

Let **k**_i be pad bit Adversary learns (**a** xor \mathbf{k}_i) and (**b** xor \mathbf{k}_i) Adversary xors those to get (a xor b), which is useful to him [How?]

Provably secure [Why?]

Usually impractical [Why? Exceptions?]

Obvious idea: Use a **pseudorandom generator** instead of a truly random pad

(Recall: Secure **PRG** inputs a seed k, outputs a stream that is practically indistinguishable from true randomness unless you know k)

Called a **stream cipher**:

- 1. Start with shared secret key k
- 2. Alice & Bob each use k to seed the PRG
- 3. To encrypt, Alice XORs next bit of her generator's output with next bit of plaintext
- 4. To decrypt, Bob XORs next bit of his generator's output with next bit of ciphertext

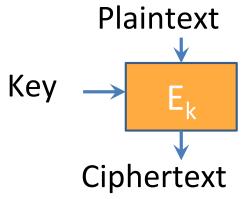

Works nicely, but: don't *ever* reuse the key, or the generator output bits

Another approach: **Block Ciphers**

Functions that encrypts fixed-size blocks with a reusable key.

Inverse function decrypts when used with same key.

The most commonly used approach to encrypting for confidentiality.

A block cipher is <u>not</u> a pseudorandom function [Why?]

What we want instead: pseudorandom permutation (PRP)

function from **n**-bit input to **n**-bit output distinct inputs yield distinct outputs (one-to-one)

Defined similarly to **PRF**:

practically indistinguishable from a random permutation without secret **k**

Basic challenge: Design a hairy function that is invertible, but only if you have the key

Minimal properties of a good block cipher:

- Highly nonlinear ("confusion")
- Mixes input bits together ("diffusion")
- Depends on the key

Definition: a cipher is "Semantically Secure"

Similar game to PRF/PRG/PRP definition:

- 1. We flip a coin secretly to get a bit **b**, random secret **k**
- 2. Mallory chooses arbitrary m_i in M, gets to see $Enc_k(m_i)$
- 3. Mallory chooses two messages $\mathbf{m'_0}$ and $\mathbf{m'_1}$ not in \mathbf{M}
- 4. If b=0, let c be $Enc_k(m'_0)$ If b=1, let c be $Enc_k(m'_1)$
- 5. Mallory can see **c**
- 6. Mallory guesses **b**, wins if guesses correctly

We can prove this follows from a PRP definition. [Fun to try!]
Also known as: IND-CPA "Chosen plaintext attack"

Today's most common block cipher:

AES (Advanced Encryption Standard)

- Designed by NIST competition, long public comment/discussion period
- Widely believed to be secure,
 but we don't know how to prove it
- Variable key size and block size
- We'll use 128-bit key, 128-bit block (are also 192-bit and 256-bit versions)
- Ten **rounds**: Split **k** into ten **subkeys**, performs set of operations ten times, each with diff. subkey

Each AES round

128-bits in, 128-bit sub-key, 128-bits out

Four steps: picture as operations on a 4x4 grid of 8-bit values

4x4 grid of 8-bit values	S _{2,0}	S _{2,1}	S _{2,2}	$S_{2,3}$
1. Non-linear step	S _{3,0}	S _{3,1}	S _{3,2}	S _{3,3}
Run each byte through a non-linear function (lookup table)				

 $S_{0,0}|S_{0,1}|S_{0,2}|S_{0,3}$

 $S_{1,0}|S_{1,1}|S_{1,2}|S_{1,3}$

- 2. Shift step: Circular-shift each row: ith row shifted by i (0-3)
- 3. Linear-mix step
 Treat each column as a 4-vector; multiply by constant invertible matrix
- 4. Key-addition step
 XOR each byte with corresponding byte of round subkey
 To decrypt, just undo the steps, in reverse order

Remaining problem:

How to encrypt longer messages?

Padding:

Can only encrypt in units of cipher blocksize, but message might not be multiples of blocksize

Solution: Add padding to end of message

Must be able to recognize and remove padding afterward

Common approach: Add **n** bytes that have value **n**

[Caution: What if message ends at a block boundary?]

Cipher modes of operation

We know how to encrypt one block, but what about multiblock messages?

Different methods, called "cipher modes"

Straightforward (but bad) approach:

ECB mode (electronic codebook)

Just encrypt each block independently

$$C_i := E_k(P_i)$$

[Disadvantages?]

Cipher modes of operation

We know how to encrypt one block, but what about multiblock messages? Different methods, called "cipher modes"

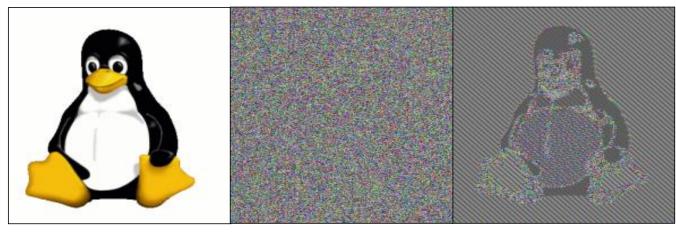

Straightforward (but bad) approach:

ECB mode (electronic codebook)

Just encrypt each block independently

$$C_i := E_k(P_i)$$

[Disadvantages?]

Plaintext

Pseudorandom

ECB mode

Better (and common):

CBC mode (cipher-block chaining)

Fake-CBC (for illustration only)

For each block **P**_i:

- 1. Generate random block R_i
- 2. $C_i := (R_i \mid | E_k(P_i \times R_i))$

[Pros and cons?]

Real CBC

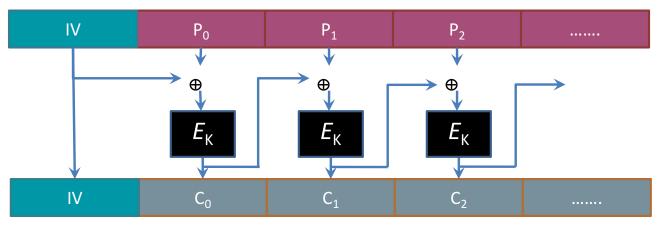

Replace R_i with C_{i-1}

No need to send separately

Must still add one random R₋₁ to start, called "initialization vector" ("IV")

Illustration: CBC Encryption

[Is CBC space-efficient?]

[Decryption?]

Using OpenSSL to do AES encryption from the command line

```
$ KEY=$(openssl rand -hex 16)

$ openssl aes-128-cbc -in mymsg.txt -out mymsg.enc
-p -K ${KEY} -iv $(openssl rand -hex 16)
key=218EEFE192DE9D46DDCF6C6D12D480DD
iv =DBB272FE6486C4D9B09DBE464E080468
```

Prints the key and IV

```
$ openssl aes-128-cbc -d -in mymsg.enc -out mymsg.txt
-K ${KEY} -iv <iv from above>
```

- By default, uses the standard padding described earlier
- Unfortunately, you have to handle prepending/extracting the IV on your own

Other modes

OFB, CFB, etc. – used less often

Counter mode

Essentially uses block cipher as a pseudorandom generator

XOR i^{th} block of message with E_k (message_id || i)

[Why do we need message_id?]

[Do we need a message_id for CBC mode?]

[Recover after errors? Decrypt in parallel?]

What is **NOT** covered by Semantic Security?

- "Malleability" attacks

Given just some ciphertexts, can the attacker create new ciphertexts that Bob decrypts the wrong value?

Encryption does NOT IMPLY integrity!

Often you really want both ("authenticated encryption")

- Chosen Ciphertext attacks

The "semantic security" definition does not allow the adversary to see decryptions of (potentially garbage) ciphertexts chosen by the adversary

Solution: Encrypt-then-MAC

Better: Use authenticated encryption modes: GCM, OCB, CCM, etc.

Assumption we've been making so far:

Alice and Bob **shared a secret key** in advance

Amazing fact:

Alice and Bob can have a public conversation to derive a shared key!

So Far

Message Integrity

Randomness / Pseudorandomness

Confidentiality: Stream Ciphers, Block Ciphers
