Programming Abstractions

Week 7-2: MiniScheme C, D, and E

Stephen Checkoway

What can MiniScheme do at this point?

MiniScheme B has constant numbers

MiniScheme B has pre-bound symbols that are in the `init-env`

What does `(parse 15)` return?

A. 15

B. `'(lit-exp 15)`

C. It's an error

What does `(parse 'z)` return?

A. `'(lit-exp z)`

B. `'(var-exp z)`

C. It's an error

What does `(eval-exp (var-exp 'z) environment)` do?

A. Returns what `z` is bound to in `environment`

B. It's an error

C. It looks up with `z` is bound to, returning the result or causing an error if `z` is not bound

D. Something else

What does `(eval-exp (lit-exp 108) environment)` do?

A. Returns what `108` is bound to in `environment`

B. It's an error

C. It looks up with `108` is bound to, returning the result or causing an error if `108` is not bound

D. Returns 108

E. Something else

Homeworks 6 and 7

Multiple steps, each adding parts to the MiniScheme interpreter

For each new type of expression
‣ Add a new data type
  - `ift-exp`
  - `let-exp`
  - etc.
‣ Add constructors, recognizers and accessors
‣ Modify `parse` to produce those
‣ Modify `eval-exp` to interpret them

```
EXP → number
    | symbol
    | ( if EXP EXP EXP )
    | ( let ( LET-BINDINGS ) EXP )
    | ( letrec ( LET-BINDINGS ) EXP )
    | ( lambda ( PARAMS ) EXP )
    | ( set! symbol EXP )
    | ( begin EXP* )
    | ( EXP EXP* )
LET-BINDINGS → LET-BINDING*
LET-BINDING → [ symbol EXP ]
PARAMS → symbol*
```

Let's add arithmetic and some list procedures
MiniScheme C

Let's add +, -, *, /, `car`, `cdr`, `cons`, etc.

Students find this to be the hardest part of the project
‣ It's the first complex part
‣ It contains some things that make more sense later, once we add lambda expressions

Many ways to call procedures

```
(+ 2 3)

((lambda (x y) (+ x y) 2 3)

(let ([f +]) (f 2 3)
```

The parser can't identify primitive procedures like + because symbols like f may be bound to primitive procedures
‣ It can't tell because the parser **does not have access to the environment**

All that the parser can do is recognize a procedure application and parse
‣ the procedure; and
‣ the arguments

Enter lists

So far, the input to MiniScheme A and B has just been a number or a symbol

If the input is a list, then the kind of expression it represents depends on the first element
- ‣ If the first element is `'lambda`, it's a lambda expression
- ‣ If the first element is `'let`, it's a let expression
- ‣ If the first element is `'if`, it's an if-then-else expression
- ‣ etc.

Applications don't have keywords, so any nonempty list for which the first element is not one of our supported keywords is an application

Procedure applications

MiniScheme C

$EXP \rightarrow$ number   parse into `lit-exp`
   | symbol   parse into `var-exp`
   | (EXP EXP^*)   parse into `app-exp`

An app-exp is a new data type that stores
‣ The parse tree for a procedure
‣ A list of parse trees for the arguments

Procedures to implement
‣ `(app-exp proc args)`
‣ `(app-exp? exp)`
‣ `(app-exp-proc exp)`
‣ `(app-exp-args exp)`

Recursive implementation
Parsing

Expressions are recursive: *EXP* → ₍ *EXP EXP** ₎

When parsing an application expression, you want to parse the sub expressions using parse

```
(define (parse input)
  (cond [(number? input) (lit-exp input)]
        [(symbol? input) (var-exp input)]
        [(list? input)
         (cond [(empty? input) (error ...)]
               [else (app-exp (parse (first input))
                              (...))])]
        [else (error 'parse "Invalid syntax ~s" input)]))
```

Parse the procedure

Parse the arguments

How should you parse the arguments?

Consider `input` that looks like
`((lambda (x y) x) 2 3)` or
`(f 4 5 6)`

The procedure part can be parsed with `(parse (first input))`

How should you parse the arguments?

Evaluating an `app-exp`

Evaluate the procedure part

Evaluate each of the arguments

If the procedure part evaluates to a primitive procedure, call a procedure you'll write that will perform the operation on the arguments
‣ E.g., if the primitive procedure is *, then you'll want to call * on the arguments

The tricky part is what does it mean to evaluate the procedure part?

Evaluating the procedure part of an `app-exp`

Consider the input `'(+ 2 3 4)`

The procedure part is `'+` which will be parsed as `'(var-exp +)`

Variable reference expressions are evaluated by looking the symbol up in the current environment

Therefore, we need our initial environment to contain a binding for the symbol `'+` (and all the other primitive procedures we want to support)

prim-proc data type

We can create a new data type prim-proc
- ‣ `(prim-proc symbol)`
- ‣ `(prim-proc? value)`
- ‣ `(prim-proc-symbol value)`

Adding primitives to our initial environment

```
(define primitive-operators
  '(+ - * /))

(define prim-env
  (env primitive-operators
       (map prim-proc primitive-operators)
       empty-env))

(define init-env
  (env '(x y) '(23 42) prim-env))
```

Evaluating an `app-exp`

Recall: `app-exp` stores the parse tree for the procedure and a list of parse trees for the arguments

We need to evaluate all of those; add something like the following to `eval-exp`

```
[(app-exp? tree)
 (let ([proc (eval-exp (app-exp-proc tree) e)]
       [args ...])
   (apply-proc proc args))]
```

eval-exp's environment parameter

Applying a procedure

The `apply-proc` procedure takes an evaluated procedure and a list of evaluated arguments

It can look at the procedure and determine if it's a primitive procedure
‣ If so, it will call apply-primitive-op
‣ If not, it's an error for now; later, we'll add code to deal with non-primitive procedure (i.e., normal lambdas)

```
(define (apply-proc proc args)
  (cond [(prim-proc? proc)
          (apply-primitive-op (prim-proc-symbol proc) args)]
        [else (error 'apply-proc "Bad proc: ~s" proc)]))
```

Applying primitive operations
(apply-primitive-op op args)

apply-primitive-op takes a symbol (such as '+ or '*) and a list of arguments

You probably want something like

```
(define (apply-primitive-op op args)
  (cond [(eq? op '+) (apply + args)]
        [(eq? op '*) (apply * args)]
        ...
        [else (error ...)]))
```

What is returned by `(parse '(* 2 3))`?

A. `'((prim-proc *) 2 3)`

B. `'((prim-proc *) (lit-exp 2) (lit-exp 3))`

C. `'(app-exp (prim-proc *) ((lit-exp 2) (lit-exp 3)))`

D. `'(var-exp * (lit-exp 2) (lit-exp 3))`

E. `'(app-exp (var-exp *) ((lit-exp 2) (lit-exp 3)))`

When evaluating an `app-exp`, the procedure and each of the arguments are evaluated. For example, when evaluating the result of `(parse '(- 20 5))`, there will be three recursive calls to `eval-exp`, the first of which is evaluating `(var-exp '-)`.

What is the result of evaluating `(var-exp '-)`?

A. `#<procedure:->` (i.e., the procedure - itself)

B. `'(app-exp -)`

C. `'(prim-proc -)`

D. It's an error because - requires arguments

What is the result of `(eval-exp (parse '(* 4 5)) init-env)`?

A. `20`

B. `'(app-exp (var-exp *) ((lit-exp 4) (lit-exp 5)))`

C. `'(prim-proc * 4 5)`

D. `'(prim-proc (var-exp *) (lit-exp 4) (lit-exp 5))`

E. `'(app-exp (prim-proc *) 4 5)`

Why go to all that trouble?

In a later version of MiniScheme, we'll implement lambda

We'll deal with this by adding a line to `apply-proc` that will apply closures

Adding other primitive procedures

In addition (pardon the pun) to `+`, `-`, `*`, and `/`, you'll add several other primitive procedures
- ‣ `add1`
- ‣ `sub1`
- ‣ `negate`
- ‣ `list`
- ‣ `cons`
- ‣ `car`
- ‣ `cdr`

And you'll add a new variable `null` bound to the empty list

What does `(car (list 3 5 2))` **parse to?**

What does `(car (list 3 5 2))` parse to?

```
'(app-exp (var-exp car)
          ((app-exp (var-exp list)
                    ((lit-exp 3)
                     (lit-exp 5)
                     (lit-exp 2)))))
```

Adding additional primitive procedures

1. Add the procedure name to `primitive-operators`

2. Add a corresponding line to the `cond` in `apply-primitive-op`

E.g.,
```
[(eq? op 'car) (car (first args))]
[(eq? op 'list) args]
```

What can MiniScheme C do?

Numbers

Pre-defined variables

Procedure calls to built-in procedures

MiniScheme D: Conditionals

Booleans in MiniScheme

In Scheme: `#t` and `#f`

In MiniScheme: `True` and `False`

You'll need to add symbols `True` and `False` to `init-env`
‣ Bind them to `'True` and `'False`

New special form: if

EXP → number   parse into `lit-exp`
    | symbol   parse into `var-exp`
    | (if *EXP EXP EXP*) parse into `ite-exp`
    | (*EXP EXP**)   parse into `app-exp`

We need a new data type for the if-then-else expression
‣ `ite-exp`
‣ `ite-exp?`
‣ `ite-exp-cond`
‣ `ite-exp-then`
‣ `ite-exp-else`

The parser
MiniScheme D

```
(define (parse input)
  (cond [(number? input) (lit-exp input)]
        [(symbol? input) (var-exp input)]
        [(list? input)
         (cond [(empty? input) (error ...)]
               [(eq? (first input) 'if)
                (if (= (length input) 4)
                    (ite-exp ...)
                    (error ...))]
               [else (app-exp ...)])]
        [else (error 'parse "Invalid syntax ~s" input)]))
```

Parsing if-then-else expressions

If-then-else expressions are recursive
‣ E.g., *EXP* → (`if` *EXP EXP EXP*)

When parsing an if-then-else expression, you want to parse the sub expressions using `parse`

The input to `parse` will look like `'(if (lt? x 1) (+ y 100) z)`

The condition is `(second input)`

The then-branch is `(third input)`

The else-branch is `(fourth input)`

Evaluating `ite-exp`

Parse tree is recursive: `(parse '(if x 10 20))`
‣ `'(ite-exp (var-exp x) (lit-exp 10) (lit-exp 20))`

When evaluating, you should call `eval-exp` recursively
‣ First, call it on the conditional expression
  - If the condition is `False`, call it on the last expression
  - Otherwise, call it on the middle expression

Can you evaluate all parts of the ite-exp?

What would happen if you instead called eval-exp on all three parts of the expression before deciding which one to return?

Think about recursive procedures using

Primitive procedures returning booleans

Numeric procedures

‣ `number?`

‣ `eqv?` Also works with `True` and `False`

‣ `lt?`

‣ `gt?`

‣ `lte?`

‣ `gte?`

List procedures

‣ `null?`

‣ `list?`

MiniScheme E: let expressions

Let expressions

Consider
```
(let ([x (+ 3 4)]
      [y 5]
      [z (foo 8)])
  body)
```

To evaluate this, we need to extend the current environment with bindings for `x`, `y`, and `z` and then evaluate `body` in the extended environment

Extending environments

```
(env list-of-symbols list-of-values previous-environment)
```

Recall that the env constructor requires
‣ a list of symbols
‣ a list of values
‣ a previous environment

The parser doesn't know anything about environments but we can create a `let-exp` data type that stores
‣ the binding symbols
‣ the parsed binding values
‣ the parsed body

Parsing let expressions

```
(let ([x (+ 3 4)] [y 5] [z (foo 8)])
  body)
```

The binding list is `(second input)` where `input` is the whole let expression

The symbols are `(map first binding-list)`

The binding expressions are `(map second binding-list)`

How can we parse each of these expressions?

The body is simply `(third input)` which we can `parse`

Evaluating let expressions

Evaluating a let expressions just takes a little more work
‣ Evaluate each of the binding expressions in the `let-exp`

```
(map (λ (exp)
        (eval-exp exp current-env))
     (let-exp-exps tree))
```

‣ Bind the symbols to these values by extending the current environment
‣ Evaluate the body of the let expression using the extended environment
