Slides from Cynthia Taylor

Announcements

- Problem Set 8 due Friday

- Lab 7 due Sunday (up tonight)

- Office Hours tomorrow 13:30 –14:30

The Processor: Datapath & Control

- We're ready to look at an implementation of MIPS simplified to contain only:
  - memory-reference instructions: `lw, sw`
  - arithmetic-logical instructions: `add, sub, and, or, slt`
  - control flow instructions: `beq`

Generic implementation

- Fetch
  - Use the program counter (PC) to supply instruction address
  - Get the instruction from memory
  - Update the program counter to the next instruction
- Decode instruction
  - Read registers
  - Use the instruction to decide exactly what to do
- Execute
  - Perform necessary data manipulation
  - Write to registers

R-Format Instructions

- Read two register operands
- Perform arithmetic/logical operation
- Write register result

a. Registers

b. ALU
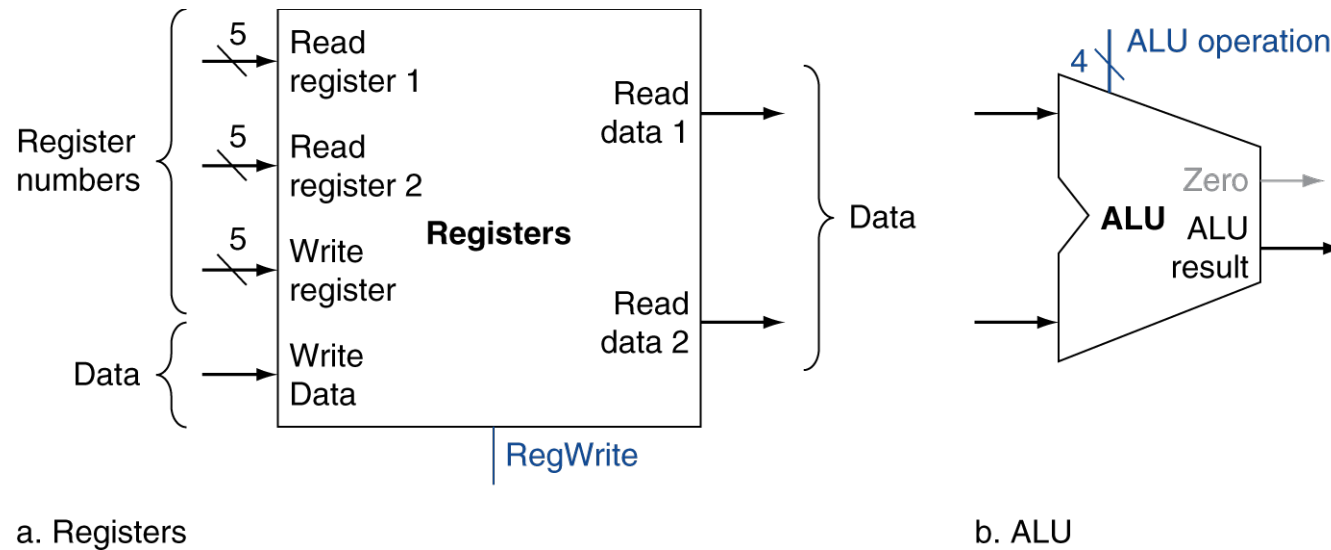

Which of these describes our interface for memory?

What do we need for

lw $t2, 0($t3) or sw $t4, 4($t5)

A. One 32-bit data output, one 5-bit select input, one 32-bit data input, two 1-bit control inputs

B. One 32-bit data output, two 5-bit select inputs, two 1-bit control inputs

C. One 32-bit data output, one 32-bit select input, one 32-bit data input, two 1-bit control inputs

D. One 32-bit data output, one 32-bit select input, two 1-bit control inputs

E. None of the above

Data Memory

- 32-bit address input

- 32-bit data to write input

- 32-bit data output

- 1-bit MemWrite control

- 1-bit MemRead control
a. Data memory unit

Load/Store Instructions

- Read register operands
- Calculate address using 16-bit offset
  - Use ALU, but sign-extend offset
- Load: Read memory and update register
- Store: Write register value to memory

a. Data memory unit

b. Sign extension unit

Which is true about the ALU and the register file in MIPS?

A. The ALU *always* performs an operation before accessing the register file

B. The ALU *sometimes* performs an operation before accessing the register file

C. The register file is *always* accessed before performing an ALU operation

D. The register file is *sometimes* accessed before performing an ALU operation
E. None of the above.
R-Type/Load/Store Datapath
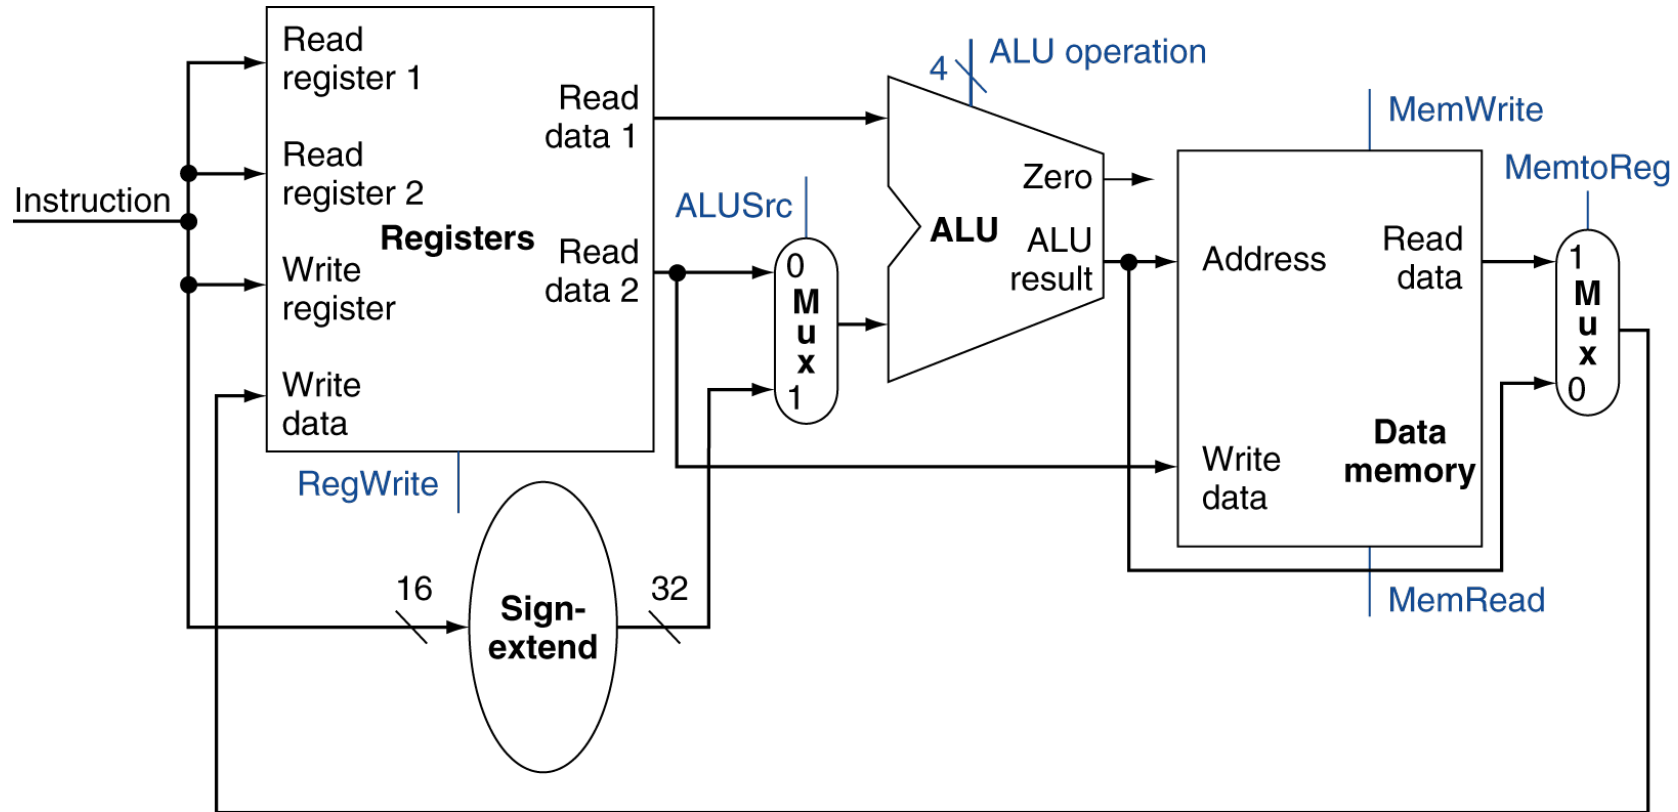

Add $t0, $t0, $t1

$t0 = 5
$t1 = 6

lw $t1, 4($t0)

$t0 = 0x07AB8110
0x07AB8114 holds 12

Conditional Branch Instructions Require

A. ALU

B. Registers and an ALU

C. Registers, ALU and Memory

D. Registers, an ALU and an Adder

beq $t2, $t3, 0x4F35

Branch Instructions

- Read register operands
- Compare operands
  – Use ALU, subtract and check Zero output
- Calculate target address
  – Sign-extend offset
  – Shift left 2 bits (word offset)
  – Add to PC + 4
    - Already calculated by instruction fetch

Branch Instructions

label:
add $s0, $s0, $t0
addi $t0, $t0, 1
beq $t0, $t1, label

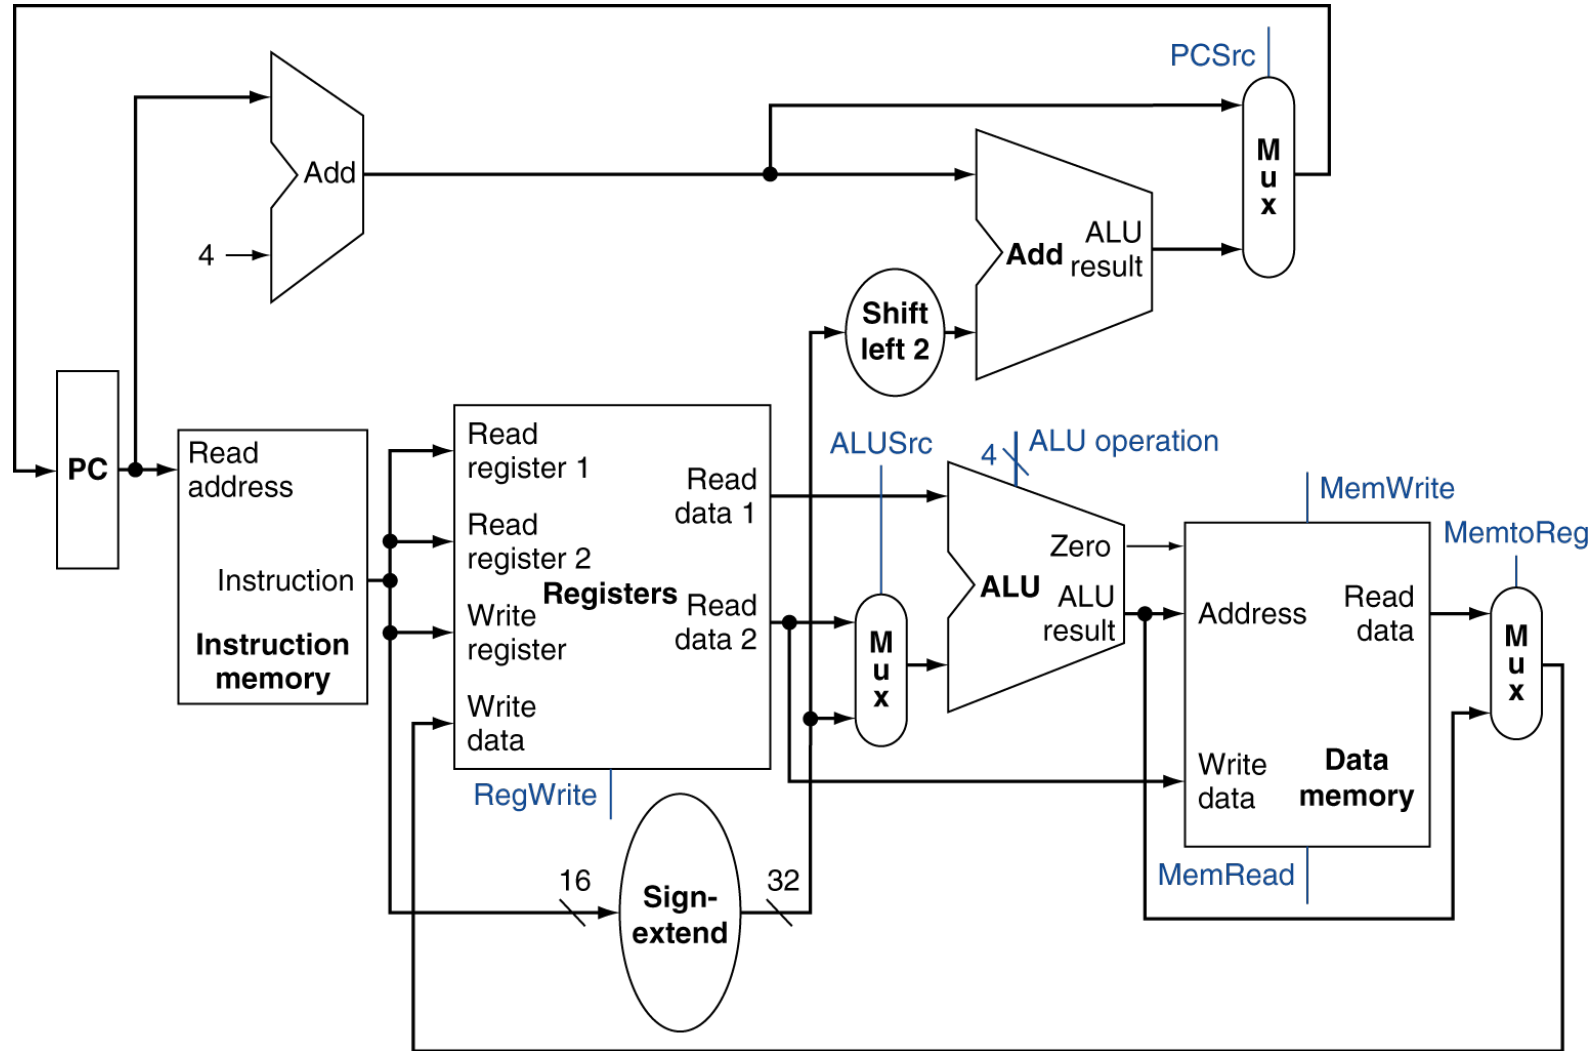

| op = 0x04 | rs = 8 | rt = 9 | imm = 0xFFFD |

Datapath (still simplified a bit)

addi $t1, $t0, -1

$t0 = 10

# What do we need to add to support ori?

Composing the Elements

- First-cut data path does an instruction in one clock cycle
  - Each datapath element can only do one function at a time
  - Hence, we need separate instruction and data memories
- Use multiplexers where alternate data sources are used for different instructions

sw $t1, 8($t0)

$t0 = 0x07AB8110
$t1 = 5

Key Points

- CPU is just a collection of state and combinational logic
- We just designed a very rich processor, at least in terms of functionality
- ET = IC * CPI * Cycle Time

Reading

- Next lecture: Control Path
  - Section 5.4

- Problem Set 8 due Friday

- Lab 7 due Sunday
